I have a component (or more) in a 3D Game. It's renderer (a GameObject that contains a MeshRenderer) is instantiated via GameObject object = GameObject.Find("MyObject"); And I want to run a method void ResetGameState() { gameState = new GameState(); gameState.SomeObject = gameState.SomeObject; } When the game is paused via GameState.HasPressedPauseButton. How would you approach this? Would you just call gameState.reset? Is there any performance impact or preformance considerations when you run FindComponent in a loop? A: The layout of your components will depend on how you generate them and so there is no clear "best way" of doing things. FindComponent can be expensive as it involves querying the depth buffer and doing a lot of maths, but it can be very quick. So if you have a very large scene then it could be expensive to use for as many components as you have. On the other hand, it could be useful for small components since you only have to query a small area. Things to consider: When you have to find multiple components in a given scene, is it more effective to use a method like FindGameObjectsForComponent such as this or a for loop? Where possible, try and cache the components you are currently querying. When you are not using components to modify scene state, you could use a global instead. Global objects such as InputManager, GameManager, Visual Studio, etc. are often either instantiated or used with static fields instead of an object instance. They are particularly useful when you don't care about component existence across the scene since you can safely operate on objects 648931e174
